Suppose we have a message to encrypt. We might choose ciphertext block chaining.

We choose a random initialization vector.

Rogaway, Wooding, Zhang (UC Davis, Thales)

-

< • • • **•**

< ≣⇒

 P_3

We whiten the first plaintext block by XORing with the IV.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 4 / 21

We feed the whitened plaintext through the blockcipher.

Rogaway, Wooding, Zhang (UC Davis, Thales)

This gives us a ciphertext block.

Rogaway, Wooding, Zhang (UC Davis, Thales)

-

< D > < B

< ∃ >

We whiten the next plaintext block using that ciphertext block, apply the blockcipher, and get a new ciphertext block.

We repeat this for all of the plaintext blocks.

But wait: what if the plaintext isn't a whole number of blocks? There'll be an odd bit left over.

We pad the partial block with zero bits.

And then whiten using the previous ciphertext block, as usual.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 4 / 21

This leaves us with the whitened odd bit of plaintext, and a *copy* of the rest of the previous ciphertext block.

It's the right width, so we can feed it through the blockcipher and get a ciphertext block.

If we decrypt that last ciphertext, we get the end of the penultimate ciphertext block back. So we don't need to transmit that part!

Addendum to NIST SP800–38A describes three variants differing in ciphertext ordering.

CBC-CS1 preserves ordering;

ъ

▶ < 글 ▶

< D > < B

CBC-CS1 preserves *ordering*; CBC-CS3 preserves *alignment* by swapping;

CBC-CS1 preserves *ordering*; CBC-CS3 preserves *alignment* by swapping; CBC-CS2 swaps only when necessary, for compatibility.

- CBC-CS3 described by Schneier (1996).
- CBC-CS3 specified in RFC2040 (1996, Baldwin and Rivest).
- All three standardized in addendum to NIST SP800–38A (2010).

Symmetric encryption syntax

We take a functional view of symmetric encryption schemes.

 $\mathcal{E}\colon \mathcal{K}\times\mathcal{IV}\times\mathcal{P}\to\mathcal{P}$

Symmetric encryption syntax

We take a functional view of symmetric encryption schemes.

 $\mathcal{E}\colon \mathcal{K}\times\mathcal{IV}\times\mathcal{P}\to\mathcal{P}$

- $\mathcal{K} \subseteq \{0,1\}^*$ is a finite *key space*;
- $\mathcal{IV} = \{0, 1\}^v$ is an *IV space*;
- $\mathcal{P} \subseteq \{0, 1\}^*$ is the message space.
- Require $\mathcal{E}_{K}^{IV}(\cdot)$ to be a length-preserving permutation on \mathcal{P} .

Symmetric encryption security: ind\$

We capture an adversary and play one of two games...

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 6 / 21

Symmetric encryption security: ind\$

$$\begin{array}{c}
IV \stackrel{\$}{\leftarrow} \mathcal{IV} \\
c \leftarrow \mathcal{E}_{K}^{IV}(m) \xrightarrow{m \in \mathcal{P}} \\
IV \parallel c
\end{array}$$

The real game: adversary chooses plaintexts *m*: we give back ciphertexts with fresh random IVs and a consistent random key.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

Symmetric encryption security: ind\$

$$\underbrace{\underbrace{m \in \mathcal{P}}_{IV \parallel c} \xrightarrow{W \notin \mathcal{IV}} c \xleftarrow{\$} \{0,1\}^{|m|}}_{V \parallel c}$$

The fake game: adversary chooses plaintexts *m*: we give back fresh random IVs and random fake ciphertexts.

The adversary's *advantage* measures how well he can distinguish between these games.

Theorem

Let \mathcal{E} be any of CBC-CS1[Perm(b)], CBC-CS2[Perm(b)], or CBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

 $\mathbf{Adv}^{\mathrm{ind}\$}_{\mathcal{E}}(A) \le \sigma^2/2^b$

Theorem

Let \mathcal{E} be any of CBC-CS1[Perm(b)], CBC-CS2[Perm(b)], or CBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

$$\mathbf{Adv}^{\mathrm{ind}\$}_{\mathcal{E}}(A) \le \sigma^2/2^b$$

Proof idea

Factor

$$CBC-CSn_K^{IV}(m) = POST_n(|m|, CBC_K^{IV}(PRE(m)))$$

Theorem

Let \mathcal{E} be any of CBC-CS1[Perm(b)], CBC-CS2[Perm(b)], or CBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

$$\mathbf{Adv}^{\mathrm{ind}\$}_{\mathcal{E}}(A) \le \sigma^2/2^b$$

Proof idea

Factor

$$CBC-CSn_K^{IV}(m) = POST_n(|m|, CBC_K^{IV}(PRE(m)))$$

• Observe that POST_n preserves uniform distribution.

Theorem

Let \mathcal{E} be any of CBC-CS1[Perm(b)], CBC-CS2[Perm(b)], or CBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

$$\mathbf{Adv}^{\mathrm{ind}\$}_{\mathcal{E}}(A) \le \sigma^2/2^b$$

Proof idea

Factor

$$CBC-CSn_K^{IV}(m) = POST_n(|m|, CBC_K^{IV}(PRE(m)))$$

- Observe that POST_n preserves uniform distribution.
- Show reduction from CBC security.

Insecurity of the Meyer–Matyas scheme

The NIST CBC ciphertext stealing schemes, for comparison.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 8 / 21

The Meyer–Matyas ciphertext stealing scheme. There's no chaining into the final partial block.

Start with a message m which is 1 bit short of two whole blocks.

The first block is whitened with a fresh random IV and fed through the blockcipher.

The second block is padded by prefixing with the final bit r of the previous ciphertext.

And then fed through the blockcipher.

But there are only two possible values for r. If we do this twice, we expect the C_2 values to be equal with probability at least $\frac{1}{2}$.

Our adversary starts with such a message.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 8 / 21

And asks its encryption oracle to encrypt it, getting a ciphertext *c*.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 8 / 21

Then it asks to encrypt the same message again, getting a new ciphertext c'.

$$\mathbf{Adv}_{\mathsf{CBC-CSX}}^{\mathsf{ind}\$}(A) = \Pr[A^{\operatorname{Real}(\cdot)} \Rightarrow 1] - \Pr[A^{\operatorname{Fake}(\cdot)} \Rightarrow 1]$$

The adversary declares 'real' if the last b bits of c and c' are equal.

If this is indeed the real game, we've just seen that they're equal with probability at least $\frac{1}{2}$.

If this is the fake game, then the ciphertexts are simply random strings.

So they're equal with probability exactly $1/2^b$.

▶ < 글 ▶

What's new about our definition

• We don't depend on chunks being single blocks, or aligned to block boundaries.

What's new about our definition

- We don't depend on chunks being single blocks, or aligned to block boundaries.
- Indeed, we don't assume there's a blockcipher involved at all.

What's new about our definition

- We don't depend on chunks being single blocks, or aligned to block boundaries.
- Indeed, we don't assume there's a blockcipher involved at all.
- Security is defined in terms of indistinguishability from random strings of appropriate lengths.

Online encryption syntax

We define online encryption schemes as functions:

 $\mathcal{E} \colon \mathcal{K} \times \mathcal{V} \times \{0,1\} \times \{0,1\}^* \to \{0,1\}^* \times \mathcal{V} \qquad (C_i, V_i) \leftarrow \mathcal{E}_K^{V_{i-1},\delta}(P_i)$

Online encryption syntax

We define online encryption schemes as functions:

 $\mathcal{E} \colon \mathcal{K} \times \mathcal{V} \times \{0,1\} \times \{0,1\}^* \to \{0,1\}^* \times \mathcal{V} \qquad (C_i,V_i) \leftarrow \mathcal{E}_K^{V_{i-1},\delta}(P_i)$

• *K* is the key space. We require that it be finite.

Online encryption syntax

We define online encryption schemes as functions:

- $\mathcal{E} \colon \mathcal{K} \times \mathcal{V} \times \{0,1\} \times \{0,1\}^* \to \{0,1\}^* \times \mathcal{V} \qquad (C_i, V_i) \leftarrow \mathcal{E}_K^{V_{i-1},\delta}(P_i)$
- *K* is the key space. We require that it be finite. *V* ⊆ ⋃_{0≤i≤v} {0,1}ⁱ is the *state* space.

Online encryption syntax

We define online encryption schemes as functions:

- $\mathcal{E} \colon \mathcal{K} \times \mathcal{V} \times \{0,1\} \times \{0,1\}^* \to \{0,1\}^* \times \mathcal{V} \qquad (C_i, V_i) \leftarrow \mathcal{E}_K^{V_{i-1},\delta}(P_i)$
- *K* is the key space. We require that it be finite.
- $\mathcal{V} \subseteq \bigcup_{0 \le i \le v} \{0, 1\}^i$ is the *state* space.
- δ ∈ {0,1} is the *end-of-message indicator*: 0 means more chunks are coming; 1 means this is the last one.
Online encryption syntax

We define online encryption schemes as functions:

- $\mathcal{E} \colon \mathcal{K} \times \mathcal{V} \times \{0,1\} \times \{0,1\}^* \to \{0,1\}^* \times \mathcal{V} \qquad (C_i, V_i) \leftarrow \mathcal{E}_K^{V_{i-1},\delta}(P_i)$
- *K* is the key space. We require that it be finite.

P

We're given a plaintext chunk.

Rogaway, Wooding, Zhang (UC Davis, Thales)

ъ

(日)

In general, we have a partial plaintext left over from the previous call. Tack this on the front.

Rogaway, Wooding, Zhang (UC Davis, Thales)

And split the plaintext into blocks. There'll be a bit left over.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 15 / 21

Encrypt the whole blocks using CBC mode, using an IV maintained in the state.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 15 / 21

The new state is the last ciphertext block, and the leftover bit of plaintext.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 15 / 21

• Of course, this is insecure. The adversary learns the IV to be used to encrypt the next plaintext chunk as part of this ciphertext.

- Of course, this is insecure. The adversary learns the IV to be used to encrypt the next plaintext chunk as part of this ciphertext.
- Suppose this is V; suppose also that the adversary guesses that the plaintext corresponding to some ciphertext C_i is P^* , i.e., that $C_i = E_K(P^* \oplus C_{i-1})$.

- Of course, this is insecure. The adversary learns the IV to be used to encrypt the next plaintext chunk as part of this ciphertext.
- Suppose this is V; suppose also that the adversary guesses that the plaintext corresponding to some ciphertext C_i is P^{*}, i.e., that C_i = E_K(P^{*} ⊕ C_{i-1}).
- So he arranges for the first block encrypted as part of the next plaintext chunk to be $P^* \oplus V \oplus C_{i-1}$. If the resulting ciphertext is C_i then his guess is confirmed.

- Of course, this is insecure. The adversary learns the IV to be used to encrypt the next plaintext chunk as part of this ciphertext.
- Suppose this is V; suppose also that the adversary guesses that the plaintext corresponding to some ciphertext C_i is P^{*}, i.e., that C_i = E_K(P^{*} ⊕ C_{i−1}).
- So he arranges for the first block encrypted as part of the next plaintext chunk to be $P^* \oplus V \oplus C_{i-1}$. If the resulting ciphertext is C_i then his guess is confirmed.
- It's sufficient to hold one block back [FMP03].

- Of course, this is insecure. The adversary learns the IV to be used to encrypt the next plaintext chunk as part of this ciphertext.
- Suppose this is V; suppose also that the adversary guesses that the plaintext corresponding to some ciphertext C_i is P^* , i.e., that $C_i = E_K(P^* \oplus C_{i-1})$.
- So he arranges for the first block encrypted as part of the next plaintext chunk to be $P^* \oplus V \oplus C_{i-1}$. If the resulting ciphertext is C_i then his guess is confirmed.
- It's sufficient to hold one block back [FMP03]. Intuition: CBC output is indistinguishable from random data, so the last block should be unpredictable, which is sufficient for security.

P

The state looks the same: previous ciphertext, and leftover plaintext.

Rogaway, Wooding, Zhang (UC Davis, Thales)

Prefix the leftover plaintext to the new chunk, split into blocks, and encrypt.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 17 / 2

We must output the previous-ciphertext block. We shouldn't output the last new ciphertext block, just store it for later.

Rogaway, Wooding, Zhang (UC Davis, Thales)

The Security of Ciphertext Stealing

March 20, 2012 17 / 21

And we keep the leftover piece of plaintext.

Rogaway, Wooding, Zhang (UC Davis, Thales)

So, we've got to the end of a message, and we've not filled up the last block.

Rogaway, Wooding, Zhang (UC Davis, Thales)

So we pad it with zero bits.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 18 / 21

The recipient can recover the tail of the next-to-last ciphertext block by decrypting the final one.

Rogaway, Wooding, Zhang (UC Davis, Thales)

March 20, 2012 18 / 21

Again, there are variants which differ in how they order the last two ciphertext blocks.

Rogaway, Wooding, Zhang (UC Davis, Thales)

• Actually the natural implementation. You have to hold back the last ciphertext block anyway, because you might have to truncate it. Indeed, for DCBC-CS3, you sometimes have to hold back *two* ciphertexts blocks.

Theorem

Let \mathcal{E} be any of DCBC-CS1[Perm(b)], DCBC-CS2[Perm(b)], or DCBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

 $\mathbf{Adv}_{\mathcal{E}}^{\mathrm{IND}\$}(A) \le \sigma^2/2^b$

Theorem

Let \mathcal{E} be any of DCBC-CS1[Perm(b)], DCBC-CS2[Perm(b)], or DCBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then

$$\mathbf{Adv}^{\mathrm{IND}\$}_{\mathcal{E}}(A) \leq \sigma^2 / 2^b$$

Proof idea

• Describe DCBC-CS*n* in terms of a DCBC oracle. (Not quite as simple as the offline case: the state needs to be structured differently, and parts of it duplicated.)

Theorem

Let \mathcal{E} be any of DCBC-CS1[Perm(b)], DCBC-CS2[Perm(b)], or DCBC-CS3[Perm(b)] and suppose adversary A asks queries totalling at most σ blocks. Then
